- 10.2 Analysing Longitudinal Data
- 10.3 Analysis Using R

We shall fit both random intercept and random intercept and slope models to the data including the baseline BDI values (pre.bdi), treatment group, drug and length as fixed effect covariates. Linear mixed effects models are fitted in R by using the lmer function contained in the lme4 package (Bates and Sarkar, 2006, Pinheiro and Bates, 2000, Bates, 2005), but an essential first step is to rearrange the data from the 'wide form' in which they appear in the BtheB data frame into the 'long form' in which each separate repeated measurement and associated covariate values appear as a separate row in a data.frame. This rearrangement can be made using the following code:

```
R> data("BtheB", package = "HSAUR")
R> BtheB$subject <- factor(rownames(BtheB))</pre>
R> nobs <- nrow(BtheB)
R> BtheB_long <- reshape(BtheB, idvar = "subject",
                          varying = c("bdi.2m", "bdi.4m", "bdi.6m", "bdi.8m"),
+
                          direction = "long")
R> BtheB_longtime \leftarrow rep(c(2, 4, 6, 8), rep(nobs, 4))
such that the data are now in the form (here shown for the first three subjects)
R> subset(BtheB_long, subject %in% c("1", "2", "3"))

3.8m	Yes	<6m	TAU	2.5	3	8	NA

The resulting data.frame BtheB_long contains a number of missing values and in applying the lmer function these will be dropped. But notice it is only the missing values that are removed, not participants that have at least one missing value. All the available data is used in the model fitting process. The lmer function is used in a similar way to the lm function met in Chapter ?? with the addition of a random term to identify the source of the repeated measurements, here subject. We can fit the two models (??) and (??) and test which is most appropriate using
